Overview

• What is bias?
• What are the main issues in bias evaluation?
  – Time frame
  – Random and systematic effects
  – Approaches for bias evaluation
• Some examples
The measurement cycle

Analytical Measurements
Tell me and I forget. Show me and I forget. Involve me and I remember.

Benjamin Franklin 1706-1790
What is bias?

- Bias is …
  1. difference between the measured value and the true value
  2. Difference between the measured value and a reference value
  3. Difference between the mean of a large number of replicate measured values and the true value
  4. Difference between the mean of a large number of replicate measured values and a reference value

For eliminating the random effects

We never know the true value

VIM: Bias is an estimate of a systematic measurement error
Bias and related concepts

Repeatability/Reproducibility

Bias

Uncertainty range of $C_i$

$C_i - U \ldots C_i + U$

$C_i - U$

$C_m$

$C_i$

$C_i + U$

Measurand, $C$

$C_{\text{Ref}}$

Reference value

Individual measured value

Mean measured value

Eurachem Workshop on Quality of Analytical Measurements
Which of these situations describe bias?

1. All the results of a specific day are systematically influenced by the calibration graph of that day

2. Delicate analyte partially decomposes during sample preparation leading to lowered results

3. The titrant concentration determined on a particular day is slightly lower or higher than the true concentration

4. Because of the specifics of the used sample preparation procedure the sample is digested incompletely, leading to lowered values
Does bias depend on the time frame?

1. Yes, bias determined within a single day is different from one determined on different days (and averaged)

2. No
Systematic and random effects

• Random and systematic effects can be grouped differently:

  - Within-day bias
  - Repeatability $s_r$
  - Long-term bias
  - Intermediate precision $s_{RW}$

  All effects causing error/uncertainty

The longer is the time frame the more effects change their „status“: systematic $\rightarrow$ random
Why is lab/method bias more useful than within-day bias?

- Within-day bias should be redetermined every day
  - Long-term bias can be determined less frequently
- It is useful to work with the lowest possible bias
  - $s_{RW}$ can be determined more reliably than bias
    - It is good if most of the uncertainty sources are included into the random component $s_{RW}$

From now on in this session we only address the long-term bias (lab/method bias)
Example: LC-MS determination of a delicate bioactive compound in blood plasma

How to conduct a spiking experiment?

• Two analysts determined meropenem (an antibiotic) in blood plasma. Both needed to determine the recovery of the procedure. They obtained blank plasma samples and did the following:

• **Analyst 1** took 500 μl of the blank plasma and added 400 μl of methanol for protein precipitation. He separated the precipitated proteins by centrifugation and transferred the supernatant into an HPLC vial. 100 μl of meropenem standard solution with suitable concentration was added to the supernatant and the resulting solution was injected into the HPLC system for analysis.

• **Analyst 2** took 500 μl of the blank plasma, added 100 μl of meropenem standard solution and mixed well. She then added 500 μl of methanol for protein precipitation. She separated the precipitated proteins by centrifugation and injected the resulting supernatant into the HPLC system for analysis.

Which analyst did it more correctly? Why?

**Analyte has to be added at as early stage as possible!**
How to evaluate uncertainty due to bias?

\[ \text{RMS}_{\text{bias}} = \sqrt{\frac{\sum (\text{bias}_i)^2}{n}} \]

\[ u(\text{C}_{\text{ref}}) = \sqrt{\frac{\sum u(\text{C}_{\text{ref}_i})^2}{n}} \]

\[ u(\text{bias}) = \sqrt{\text{RMS}_{\text{bias}}^2 + u(\text{C}_{\text{ref}})^2} \]

This component accounts for the average bias of the laboratory results from the \( \text{C}_{\text{ref}} \)

This component accounts for the average uncertainty of the reference values \( \text{C}_{\text{ref}} \)
5.3. SOURCES OF UNCERTAINTY

**Brief summary:** The overview of possible uncertainty sources, relevant to pesticide analysis, is presented. Most of the uncertainty sources are linked to specific steps in the analysis procedure. It is stressed that sample preparation is usually the biggest contributor to measurement uncertainty. When performing chemical analysis, every care should be taken to minimize (preferably eliminate) the influence of the uncertainty sources, as far as possible. And what cannot be eliminated, has to be taken into account. It is not necessary to quantify every uncertainty source individually. Instead, it is often more practical to quantify several uncertainty sources jointly.
